APPENDIX D

FLAME TEST AID TO IDENTIFICATION OF PLASTICS

# Identifying Rigid Plastic Containers

Plastics Group, The Dow Chemical Company 2040 W.H. Dow Center, Midland, MI 48674

January 1989

This table can be used to identify the plastic used in rigid plastic containers. With only a glass of water, knife and match, anybody can determine the plastic with a very high degree of accuracy.

For example, if you put a piece of the "unknown" plastic in a glass of water and it sank, you would know the plastic was polyvinyl chloride or polystyrene (unless the container was a soft drink or miniature liquor bottle). If the plastic sank and didn't burn, then you could be assured that the bottle was produced from polyvinyl chloride.

Multi-layer, multi-component containers cannot be accurately identified by this system. However, these containers are a small percentage of the total market.

Referring to the list of "Typical Packaging Containers" on the reverse side of this page makes it even easier to identify plastics.

|                                                           |                                   |                   | Type of         | Plastic                           |                                   |                                                  |

'Use caution when striking the match and attempting to ignite the piece of plastic. Keep the glass of water handy to quickly axtinguish the burning piece of plastic. Remember that burning plastic may drip. The hot droplets will burn flesh and can mar surfaces.

APPENDIX G

GLOSSARY OF TERMS

1

#### **GLOSSARY OF TERMS**

ABS---acryl butyl styrene; a dense plastic found in, e.g., computer housings, telephone casings, pipe;

absorb---(in the sense used in the present report) the uptake or penetration of water or other solvent into the interstices of a chemical matrix, i.e., not unlike the uptake of water by a dry sponge;

accuracy---in a statistical sense, the term gives an indication of the <u>closeness</u> of the results, estimates, etc. to the "true" value.

adsorb---the adherence of water or solvent to the surface of an object, without penetration into the "interior", ie., a 'film' of moisture;

BTU---British Thermal Unit; the amount of heat required to raise the temperature of 1 pound of water 1 Fahrenheit degree ; in this case, the "potential energy" or the amount of heat that would be released from the material if it were to be burned (usually rated calories per unit weight of material - SI units: kiloJoules per kilogram);

commercial wastes---discarded materials generated by commercial businesses as a result of normal activities in the workplace;

ferrous---a metal object containing elemental iron, giving a `positive' or attractive response to a magnet;

MSW---municipal solid waste, usually defined as the sum of residential and commercial solid wastes, and <u>excluding</u> industrial wastes;

non-ferrous---a metal object which does not give a 'positive' or attractive response to a magnet, e.g., copper, brass, lead, aluminum, etc.

G - 1

OCC---old corrugated containers; variously called, old corrugated cardboard;

PET---polyethylene terephthalate; the plastic used to manufacture the common 2 litre pop bottles;

polyolefin---in the sense used here, a grouping of chemically related plastics whose chemical building blocks are either ethylene or propylene;

precision---in a statistical sense, the term gives an indication of the <u>repeatability</u> of a series of observations, estimates, etc. The Standard Error is one kind of estimate of the precision or repeatability or "tightness" of the grouping of the observations (=data);

putrescible---a material which is biodegradable; usually a term reserved for animal or vegetable matter;

PVC---polyvinyl chloride; a plastic containing chlorine; well known as siding, plastic window sashes and frames, pipe and a few rigid containers;

residential waste---discarded materials generated by individuals in the course of their daily activities at their place of residence; in this case, exclusive of yard wastes and leaves;

tare weight---the weight of an empty container;

### DISCLAIMER

This report was prepared for the Ontario Ministry of the Environment as part of a Ministry-funded project. The views and ideas expressed in this report are those of the author and do not necessarily reflect the views and policies of the Ministry of the Environment, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

study, in which the crew unloaded the refuse bins by hand to determine the total weight of the waste in the bin.

5. During the course of the study, insights were noted regarding the effectiveness of waste management practices of some firms. For example, for automotive repair businesses, it appears that employee's tend to use the general refuse bin for discarding metal waste materials, despite the fact that a scrap metal bin has been made available.

Such insights, when communicated to the management of the firm provide an immediate opportunity to help that firm improve the efficiency of their recycling efforts.

There is also an indication that differences exist in per employee waste generation rates in small grocery stores and in larger supermarkets.

The demonstrated method for estimating the rate of employee waste generation has the potential to be used as a waste management tool by municipalities. The distribution of the daily waste generation rates versus employment data, exhibited in the graphs for each SIC sector, could enable municipal waste management personnel to prioritize their "remedial" waste reduction efforts by planning to visit those companies whose waste generation rates seem out of line with the general waste-to-employee relationship.

### Recommendations

The methods employed in the commercial portion of the Ontario Waste Composition Study have been demonstrated on a selection of commercial businesses in the Regional Municipality of Waterloo. Within the commercial sectors in the Region there is a relatively high awareness of waste diversion options that will reduce waste disposal costs and encourage recycling. Therefore,

xv

The total annual tonnage received by the two Region of Waterloo landfill sites in 1989 was 439,000 tonnes. Based on the results of the present study, the commercial sector contributed an estimated 76,388 tonnes, or 17.4% of the total weight.

2. The most commonly encountered waste material in commercial refuse was corrugated cardboard (OCC) which ranged from a low of 4.0° to a high of 49.0% of the weight of refuse generated by the firms which were sampled.

The wide range in OCC content may be the result of some firms separating used OCC for recycling, possibly in anticipation of the proposed ban on the landfilling of OCC within the Regional Municipality of Waterloo in 1991.

Variations observed in the composition of other waste streams may be due to recycling activities, either under the auspices of company-wide programs or by conscientious employees who took materials to recycling locations in the municipality or home to their own Blue Boxes.

- 3. The statistical reliability of the waste composition data for some of the SIC groups is questionable because of the small number of waste samples that were sorted. Nevertheless, the data indicate the general proportion of materials in the waste streams from the 16, two-digit SIC groups that comprise the commercial business community in the Region. Waste from 65 businesses was sorted.
- 4. The installation of a truck-mounted scale, used to determine the weight of refuse in 2 to 8 cubic yards refuse bins, enabled us to obtain waste quantity data from an additional 80 commercial businesses. For estimating the per employee waste generation rates, this method is more efficient than the labour intensive method, used in the waste composition part of the

xiv

### INFORMATION FOR THE READER

The results of the Ontario Waste Composition Study appear in three volumes.

Volume I contains the results of the residential portion of the Ontario Waste Composition Study. The emphasis in Volume I is on the development and testing of a method that municipalities can use to estimate per capita generation rates of residential refuse. The field work for Volume I took place in East York, Fergus, and North Bay, Ontario.

Volume II contains the results of the commercial portion of the Ontario Waste Composition Study, which are presented herein. Waste generation data for two light industrial businesses are also provided in Volume II. The emphasis in Volume II is on the development and testing of a method that municipalities can use to estimate per employee waste generation rates and, further, to estimate the quantity of waste generated from all commercial sources. The commercial component of the study took place in the Regional Municipality of Waterloo.

Volume III is a "user friendly" manual that outlines the procedures for conducting residential and commercial waste composition studies in municipalities of Ontario.

(i)

#### ABSTRACT

Volume II, the Commercial Waste Composition Study, is the second of the three volumes comprising the Ontario Waste Composition Study.

The commercial study was conducted in the Regional Municipality of Waterloo between May 15 and August 31, 1990. The study focuses on developing a cost effective method for conducting waste composition assessments, estimating per employee waste generation rates in commercial businesses and estimating the waste generated by the entire commercial sector in a municipality.

Statistics Canada, as part of their Standard Industrial Classification (SIC), has disaggregated the universe of economic activity in Canada into 18 divisions. The same classification is used for all of Statistics Canada's economic surveys. The SIC provides the basis for the selection of commercial activities to be studied, and for the extrapolation of sample results into municipal totals.

Within this universe of activity, the commercial waste composition study focuses on six divisions whose activities take place within the private sector and serve local communities. As these commercial activities are located within the communities they serve, the number and size of these activities can be readily predicted from a knowledge of the size and characteristics of the residential population.

Statistics Canada further disaggregates these six divisions of commercial activity into 27, two-digit SIC codes, each representing a familiar group of retail or service activities. In order to get the most information from a limited number of samples, these two-digit groups were further aggregated and disaggregated. The idea here was to aggregate those groups that appeared to have similar waste generation patterns, and to disaggregate those that had varied rates of waste generation. For example, the automotive group was disaggregated to reflect fundamentally different

(ii)

kinds of operations in dealerships, garages and gas stations. Among financial services, only banks were sampled.

Waste composition information (65 separate collections) and per employee waste rates (212 samples) were obtained for representative commercial businesses. Per employee waste generation rates were estimated from regression analyses or data averaging.

Estimated average employee waste generation rates for each disaggregated commercial activity were multiplied by total Regional employment in the activity to obtain estimates of waste generation for the activity. The latter estimates were summed to give a total estimate of waste generated by commercial businesses in the Region.

The study did not include schools (see Volume I), hospitals and other health care facilities, government offices or wholesale activities. However, two "light" industries were sampled.

### EXECUTIVE SUMMARY

The two-fold purpose of the Commercial Waste Composition Study was to:

- develop a simple, cost effective and reliable method for determining the composition and per employee generation rate of waste from commercial sources in Ontario (the study concentrated on that portion of the commercial waste stream that can be closely related to residential waste; that is, both waste streams stem from the same processes of consumption); and
- 2. apply the method and obtain current information on the characteristics of commercial waste streams.

A review of relevant literature and consultation with experts in the fields of employment, commercial structure, demographics and waste management indicated that commercial waste generation is related to the number of employees at a particular commercial establishment.

Commercial activity in Canada is organized by the Standard Industrial Classification (SIC) established by Statistics Canada. This classification was used as the basis for reporting waste composition and per employee generation rate data. Before the field study began, the commercial business SIC codes were reviewed with respect to retail service activities to determine whether certain sectors could be grouped together.

The Census of Canada (1986) gathered information about occupation, type of employment and place of work from a twenty percent (20°°) sample of households. These data provide information about the number of employees in 36 different commercial sectors within each of the urban census areas in Ontario. This kind of information was gathered for the Regional Municipality of Waterloo, including the Cities of Kitchener, Waterloo and Cambridge, and the Townships of

Woolwich, Wilmot, Wellesley and North Dumfries. The field study was undertaken in the Region between May 15 and August 31, 1990.

A representative sample of businesses from the SIC groupings were identified and approached by the study team to gain permission to include them in the study. Data were then gathered on the composition of the waste stream from each SIC grouping, and an estimate of the average generation rate of total waste per employee was made for each of the SIC groupings. Sixty-five businesses were analyzed for both waste composition and per employee waste generation rates. Eighty additional companies were sampled only to obtain per employee waste generation rates. Some companies of the latter group were sampled twice for a total of 212 samples forming the per employee waste generation data base of this study.

The relationship between waste generation and employment was completed by regression analysis when the characteristics of the data set, (eg. sample size) permitted. In other cases an average of the waste generation data is reported where regression analysis was deemed inappropriate.

Estimated average per employee waste generation rates for each commercial activity were multiplied by the total Regional employment in the activity to obtain estimates of the waste generation for the activity throughout the entire Region.

### **Conclusions**

1. Waste composition and per employee generation rates have been estimated for the commercial businesses in the Regional Municipality of Waterloo. The methods used in the present study provides direct estimates for 52° of of the total employment in commercial business in the Region and indirect estimates for 100%. Thus, estimates of the waste generated by a segment of the commercial sector of the municipality have been made for the first time.

xiii

we cautiously regard the qualitative and quantitative data presented herein as a best estimate under constantly changing circumstances.

This report has developed a procedure for estimating the amount of waste generated by commercial activities within Ontario urban areas and began with the process of integrating the complex data inputs required. What are the next steps?

The study has employed a two-stage estimation process: (1) the development of ratios of waste generation per employee; and (2) the estimation of commercial employment composition for the municipality as a whole. Each step poses different problems. The following recommendations are submitted:

1. The waste generation and composition data base will require many more samples in order to cover the full range of commercial activities. No one study will have the resources to undertake a complete evaluation; the research results must be accumulated over many studies and evaluated over time. Fortunately, there is no inherent reason that a business in any part of the province cannot be used to estimate waste generated elsewhere--unless local waste management policies differ significantly.

This means that each study should use the same SIC identification to code commercial activity and the same methodology for measuring waste output and composition. A central agency (e.g., the Ministry of Environment) may have to take the responsibility for organizing and evaluating the data.

2. It will also be necessary to monitor any changes over time in waste generation that may reflect innovations in policy, technology or corporate behaviour. The date of each sample must be retained and or it may be necessary to identify sample locations that can be restudied over time in order to minimize sampling error.

xvi

- 3. To better understand the effect of recycling behaviour on the data gathered, it is recommended that employees management of participating firms be asked to describe the nature and extent of any source separation recycling activities.
- 4. The immediate priorities for sampling can be identified from the results of this study. Those commercial activities that employ large numbers of people must be further investigated in order to improve sample size and reveal any significant variation within the SIC groups; this includes the diverse set of office and financial activities. Conversely, those activities with a high rate of waste generation per employee, such as food stores and restaurants, must be sampled repeatedly because of their importance to the overall waste generation. Those sectors where the observed sample variance (standard deviation) is high require larger samples to improve overall accuracy, possibly by isolating subgroups within the SIC. Activities that generate policy-relevant waste materials should be given special attention.
- 5. The future development of employment estimates requires two divergent approaches. First, substantial savings may result from a centralized, standardized analysis of employment that applies the same set of data, techniques and projections to all urban areas--much as the Ontario Statistical Centre has developed a common set of population forecasts.

At the same time, municipalities have better information about local peculiarities and exceptions to the employment structure. These special cases, e.g., community colleges, tourist attractions, shopping concentrations, as well as manufacturing activities, may require special attention by a local agency.

SECTION 1

# INTRODUCTION & LITERATURE REVIEW

### 1.0 INTRODUCTION & LITERATURE REVIEW

#### 1.1 Introduction

In recognition of a pressing need to improve the way in which waste is managed in Ontario, the Ontario Ministry of the Environment has initiated programs and established specific goals designed to ensure the development of innovative and integrated waste management systems. For example, the Ministry has issued Terms of Reference and assisted in the funding of Waste Management Master Planning for municipalities. Specific objectives for diverting significant amounts of waste from disposal through reduction, reuse and recycling activities (25° by 1992 and 50% by 2000) have also been announced by the Government of Ontario.

In order to effectively plan and design waste management systems that will achieve those goals, reasonably accurate estimates of the types and quantities of waste must be available. For example, the design of material recovery facilities that will receive and process waste must be compatible with the range of wastes anticipated to be received by the facility.

The Ministry of the Environment contracted Gore & Storrie Limited, in association with Decima Research Limited, to develop and test methodologies that would assist waste management planners and municipalities in deriving reasonable estimates of the material composition and generation rate of wastes from residential and commercial sources. The results of that study are presented in three volumes:

| Volume |    | - | Residential |        |
|--------|----|---|-------------|--------|
| Volume | 11 | - | Commercial  |        |
| Volume | IH | - | Procedures  | Manual |

The results of the commercial portion of the Ontario Waste Composition Study are presented herein, and describe the development and field trial of a methodology for estimating the type and quantity of waste generated by a variety of different types of commercial enterprises; i.e., those firms in the private sector that provide goods and services for consumers. Although these activities may be concentrated at a small number of locations within the urban area, such as "downtown", or a regional mall, the aggregate amount of commercial activity is very closely related to both the number of households and household income in the urban area. Commercial waste, in this sense, can be closely related to residential waste. Both waste streams stem from the same processes of consumption.

The Study focused on the commercial activities that are most closely linked to residential requirements. The waste generation from office buildings is an important component; but it is difficult to distinguish offices that serve local residents (e.g., a lawyer) from those that serve the province as a whole (e.g., an insurance firm). Wholesale activities, while part of the commercial waste system, also serve larger spacial units. They are too varied in their size and function to fit into the present sampling framework. They must be studied elsewhere, when a community studies the entire waste stream in their area. A review of relevant literature and consultation with experts in the fields of employment, commercial structure, demographics and waste management indicated that commercial establishment.

The plan for the Study was developed during the winter of 1989 1990. The study uses the extensive information on the amount and composition of commercial employment provided by Statistics Canada and local government agencies to define a sampling framework for the field work.

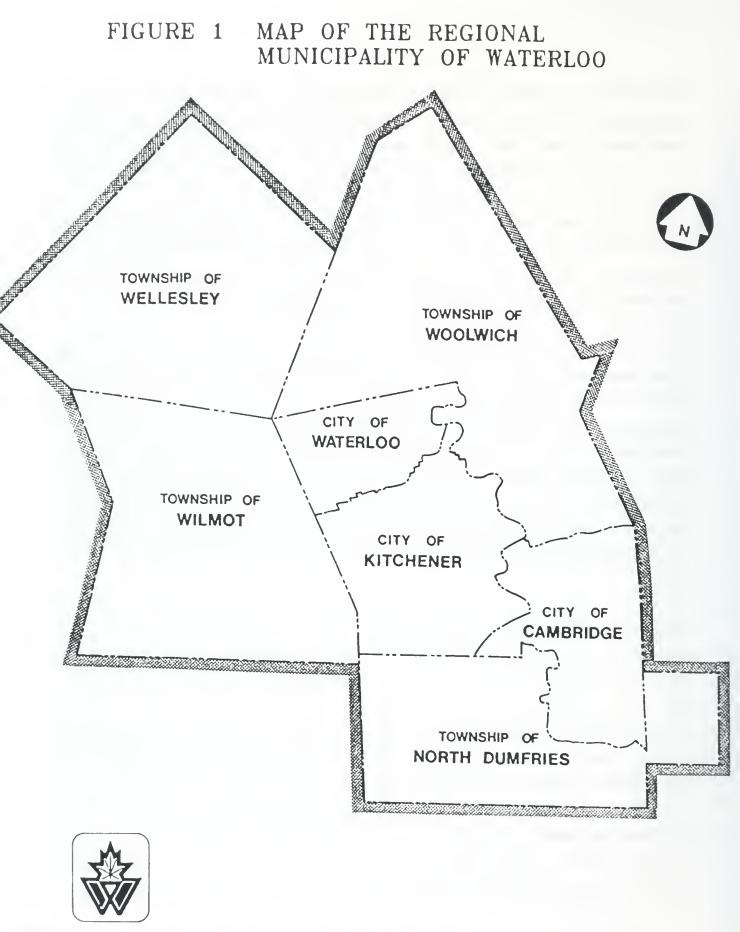

Commercial activity in Canada is organized by the Standard Industrial Classification (SIC) established by Statistics Canada. This classification was used as the basis for reporting waste composition and per employee generation rate data. Before the field study began, the commercial business SIC codes were reviewed with respect to retail service activities to determine whether certain sectors could be grouped together.

The Census of Canada (1986) gathered information about occupation, type of employment and place of work from a twenty percent (20°°) sample of households. These data provide information about the number of employees in 36 different commercial sectors within each of the urban census areas in Ontario.

Figure 1 is a map of the field study area which is the Regional Municipality of Waterloo, including the Cities of Kitchener, Waterloo and Cambridge, and the Townships of Woolwich, Wilmot, Wellesley and North Dumfries. The field study was undertaken in the Region between May 15 and August 31, 1990.

A representative sample of businesses from the SIC groupings were identified and approached by the study team to gain permission to include them in the study. Data were then gathered on the composition of the waste stream from each SIC grouping, and an estimate of the average generation rate of total waste per employee was made for each of the SIC groupings. Sixty-five businesses were analyzed for both waste composition and per employee waste generation rates. Eighty additional companies were sampled only to obtain per employee waste generation rates. Some companies of the latter group were sampled twice for a total of 212 samples forming the per employee waste generation data base of this study.

This report establishes a methodology for measuring waste generation and waste composition for commercial activities, as defined above. For a number of reasons, the study of waste generation by these activities is a much more complex problem than that of residential activities reported in Volume I of the Ontario Waste Composition Study. First, very little published research is available for commercial activities (none for Canada in recent years) and therefore the research team had little <u>a priori</u> knowledge of expected values or variance to guide the design of an efficient sampling framework. Second, as apparent in the discussion of the results, commercial activities are characterized by very high variance, relative to the residential sector. That variance is observed in waste generation both within and among the various retail and service sectors. There was also a wide range in

REGIONAL MUNICIPALITY OF WATERLOO DEPARTMENT of PLANNING and DEVELOPMENT

store size (measured in level of sales or employment) within these sectors that must be taken into account. These variations mean that a much larger number of samples are required in order to provide the same degree of reliability obtained in the study on residential waste generation. Third, while detailed descriptions of household characteristics are provided by the <u>Census of Canada</u>, together with a variety of forecasts of growth and change provided by market research firms and government agencies, it is difficult to identify even the base population for a sample of commercial activities. It is not common for a single data source to provide counts or lists of the number of supermarkets or barber shops within a municipality. Sample locations must be identified in the field; extrapolations to obtain municipal or regional totals now and in the future require elaborate assumptions and indirect procedures.

Nonetheless, the report describes a workable method, and provides sufficient data to support an overall estimate of waste generation for the Region, together with the major components of the waste stream. While many more sample points will be required to increase the precision of estimates of waste streams for specific commercial activities, studies at the municipal level benefit from the effect of aggregation in which hundreds or thousands of activities are averaged together. The report also provides a methodology for future studies that overcomes each of the difficulties identified earlier. Data on commercial waste generation and composition are now available to guide the design of waste sampling procedures. The identification of high waste generation activities in this study permits agencies to target waste reduction and recycling programs on these activities. The difficulties, due to varying store size and unavailable data on the population of stores, have been overcome by focusing on number of employees as the key measure that connects the sample observation to the overall data analysis and ultimately to the aggregate waste generation by the municipality. The number of employees in each SIC code is listed by Statistics Canada in their data base.

It would have been possible to restrict the study to just a few well chosen SIC groups in order to achieve greater confidence in the waste estimates. However, we

chose a broader study in order to assess the variances encountered in various SIC groups. This choice benefits subsequent workers who can target their efforts to develop and enhance a data base of waste generation for commercial activities in Ontario.

#### 1.2 Literature Review

The Bird & Hale report (ref. 2) has been used as the baseline study for waste composition information on the municipal solid waste stream in Ontario. In the Bird & Hale study, the average annual composition of municipal solid waste entering landfill sites, transfer stations and incinerators, in Toronto, was derived from samples obtained during spring, summer, winter and fall. Twelve visits were made to six sites between October, 1976 and September, 1977, with two visits apiece at: Commissioners Street Incinerator, Ingram Incinerator, Dufferin Incinerator, Beare Road Landfill Site, Bermondsey Transfer Station and Wellington Incinerator. Sample weights of municipal solid waste ranged up to 400 lbs. (180.7 kg).

Municipal solid waste has been traditionally defined as a combination of waste from residential and commercial sources, so the Bird & Hale study--which collected and reported on this combined municipal solid waste data--does not serve as a suitable baseline for the present work which focuses on the commercial activities that are related to residential consumption.

The earliest studies of the composition of commercial solid waste were reported by Peter Middleton & Associates (ref. 11). They briefly described three studies: Louisville (1970), Proctor & Redfern (1972) and Proctor & Redfern (1975), each based on questionnaires sent out to commercial businesses. The Louisville study reportedly divided the commercial sector into 18 different categories but regrettably this detail was not provided in the main report or appendix. The same is true of the two Proctor & Redfern reports. The questionnaires reportedly contained information on the categories of commercial businesses, but the information was reportedly lost (ref. 11).

Franke (ref. 5) described the general composition of the commercial waste stream in Cologne, Germany (1980.81 data) and Evans (ref. 4) reported the weight and volume of components in the waste streams from "retail", restaurants and office towers in Toronto (1984 data). More recently, Rhyner & Green (ref. 14) compared published literature data on per capita or per employee waste generation rates for residential, commercial, industrial and construction demolition wastes with actual waste data that they were obtaining at county-owned landfill sites in Brown County, Wisconsin. Annual solid waste generation estimates were calculated for a number of SIC codes in the commercial sector. Rhyner & Green's estimates of the annual generation of commercial refuse, using a daily employee generation rate of 0.73-0.77 kg and county employment data, was within 15% of the "actual quantity". Table 1 summarizes the available information on the composition of commercial waste streams, from sources reported above.

A key paper that became the basis for the data gathering procedures developed in the present study was published in 1971 by DeGeare & Ongerth (ref. 3). The authors explored the relationship between waste generation in clothing, drug, grocery, hardware stores, and restaurants as a function of a number of variables indicative of the physical and operational characteristics of commercial establishments. For example: (1) number of hours open per week; (2) number of business days open per week; (3) average annual gross receipts; (4) physical area of store, in square feet; (5) average inventory in dollars; (6) equipment value, in dollars; (7) number of delivery days per week; and (8) number of employees. Number of employees and store hours were the two variables that gave the best prediction of the waste generation rate for premises in the commercial sectors under study.

DeGeare and Ongerth, using "multiple stepwise regression analyses", demonstrated that the generation of commercial solid waste was found to be most closely related to the number of employees, hours open, and type of establishment involved. Graphs illustrating the correlation between actual and predicted waste quantities from the DeGeare and Ongerth study are reproduced in Appendix A.

<sup>&</sup>lt;sup>1</sup> Data are given as percentages of the commercial waste stream. Canadian studies: Proctor & Redfern (1972; 1975), Evans (1985); U.S.A. studies: 2 Louisville (1970), Liblit (1990); Germany: Franke (1987). 2 Includes 12% construction wastes

Two points will clarify the relationship between waste generation and company employment. First, employment is a function of the intensity of retail activity; i.e., a small store with few customers will require a smaller sales staff than a larger store that serves a large clientele. Second, the items sold by stores are delivered in bulk, in packages, cartons, and other containers, with the individual items placed on shelves or otherwise displayed. Taken together, we see that as the size of a store's staff increases to serve increasing numbers of customers (and sales), the quantity of goods delivered to the store will grow in response to customer demand and the amount of bulk packaging and related administrative wastes will also increase.

The focus on waste generation per employee that is evident in the literature fits well with another reference that examines consumer behaviour and commercial structure This reference demonstrates that the amount of (Jones & Simmons, ref. 8). commercial activity is highly predictable from information about the size and income level of the market. Given the number of households and average income level in any city, it is possible to project first, the patterns of consumer expenditure, from toothpaste to bank deposits, in great detail; and second, to calculate the level and composition of commercial activity. Furthermore, the different measures of commercial activity (i.e., number of stores, floor area, retail sales, number of employees) are all closely interrelated. Employment happens to be the most frequently measured and readily obtained. It provides the key link between the samples from the field work and the larger municipal waste system. When one determines the waste generation per employee for a SIC group, this generation rate can be extrapolated, via Statistics Canada data on total employment in the SIC sector to get the waste generation rate for the entire company. It is then possible to determine whether a reasonable amount of waste is being disposed at a given company as compared to an average waste generation rate for a company of similar size in the same SIC sector.

The authors would like to point out that they discovered a paucity of information pertaining to this subject and have made every attempt to locate and examine all relative material.

### 2.0 METHODOLOGY

### 2.1 <u>Overview</u>

The general approach used in the study included the following steps:

#### A. Selection of Commercial Businesses

The commercial business SIC codes were reviewed with respect to retail service activities to determine whether certain activities could be grouped together. Although the commodities or services provided by businesses may differ, similarities in the waste streams permitted aggregation of sectors, and reduced the requirement for field work.

### B. Development and Implementation of the Waste Sampling Program

- (1) Information on the composition of the waste stream from each SIC group was obtained.
- (2) An average generation rate of total waste per employee for each of the commercial groups was estimated. Waste was collected from a number of premises in each SIC group, attempting to cover a range of small and large companies. The relationship between waste generation and employment was assessed by regression analyses when sample size permitted.

# C. Development of a Region Employment Profile for Commercial Activities

Statistics Canada employment data and the Region of Waterloo's planning information were analyzed to generate an estimate of the total number of people employed in the commercial groupings for which waste generation estimates were obtained.

\*\* High emphasis in study

# D. Estimation of Waste by Commercial Activities in the Region

Regional employment was multiplied by the employee waste generation rate for each SIC group to estimate the quantity of waste generated by each of the commercial activities. The sum of the waste estimates for the groups gave an estimate of waste generation by a large segment of the commercial sector in the municipality.

# 2.2 Commercial Employment in the Regional Municipality of Waterloo

### 2.2.1 Defining Commercial Activity

Statistics Canada, as part of its Standard Industrial Classification (SIC), has disaggregated the universe of economic activity in Canada into 18 groups (ref. 15). Thus, the classification provides the basis for the selection of commercial activities to be studied, and for the extrapolation of the sample results into municipal totals. The same classification is used for all of Statistics Canada's economic surveys. It enables us to apply data from the <u>Census of Canada</u>, or the monthly <u>Labour Force Survey</u>, to the task of estimating waste generation for aggregations of commercial activities.

Within this universe of activity, the commercial study focused on six divisions: J, K, L, M, Q, and R (Table 2). The activities in these divisions take place within the private sector and serve local residential communities. Thus they are located within the communities they serve, and the number and size of these activities are quite predictable from a knowledge of the size and characteristics of the residential population. Within these six divisions, Statistics Canada identifies hundreds of smaller groups of specialized activities each of which includes a large number of stores that provide similar goods and services and operate in the same fashion. Given a base population of activities, these stores can be sampled and extrapolated to provide overall estimates of waste generation.

 $^1{\rm Retail}$  hardware and building supplies are designated as wholesale activities in the SIC classification

In contrast, the primary manufacturing and wholesaling divisions are fewer in number and far more diverse in size and specialization. This is because they are not directly tied to or restricted by the size and requirements of <u>local</u> markets; i.e., those in close spatial proximity to the manufacturing or wholesaling activity. A factory may produce goods for markets across the continent using processes and materials that are quite different from a neighbouring plant--even if the plant has the same industrial classification. Some municipalities have many factories; others have virtually none. Waste generation by such activities must be studied on a site-bysite basis.

While many educational, health, and local governmental services serve local residents, some activities, such as universities or major hospitals, have been excluded from this study. As well, the lawn and yard maintenance service sector was not sampled in the present study.

The six divisions in this study include 32.8 percent of the total employment in the Regional Municipality of Waterloo. Divisions J and Q, which were sampled most thoroughly, include 18.1 percent of the total. Commercial activities are numerous and represent a significant component of the economic base of every community.

Statistics Canada further disaggregates these six divisions of commercial activity (which are included in the study) into 27, two-digit SIC codes, each representing a familiar group of retail or service activities. In order to get the most information from a limited number of samples, these two-digit groups were further aggregated and disaggregated as shown in Table 3. The general principles applied here were to aggregate those groups that appeared to have similar waste generation patterns, and to disaggregate those that had varied rates of waste generation. For example, the automotive group (SIC 63) was disaggregated to reflect fundamentally different kinds of operations in dealerships, garages and gas stations. Group 64 was estimated from the results for groups 61 and 62. Among financial services, only banks were sampled.

different waste generation patterns could be identified. The final results will identify further sub-groups which are discussed later.

In addition, a limited number of samples explored economic activities lying outside the targeted divisions. Building supply stores (SIC 56) were sampled within the framework, but are formally classified as wholesale activities within the SIC. They are excluded from the expansion of the sample for the municipal total. The printing and publishing manufacturing group (SIC 28) was also sampled.

### 2.2.2 Extrapolation of Sample Data to a Municipality

The problem of extrapolating the results from the waste generation samples to project the waste generation for an entire area or regional municipality is complicated by the lack of information that describes the overall magnitude of commercial activity. There is no <u>Census of Retail and Service Activity</u>, or its equivalent. Instead, data on commercial employment obtained from several different sources must be adapted to the problem. It should be underlined that the procedures used for this extrapolation may vary from place to place, depending on the mix of information that is available.

The starting point is the <u>Census of Canada, 1986</u> (soon to be superseded by the 1991 version) for the residential population. For a twenty percent sample of households, each person over 15 is asked about employment; e.g., what kind of firm? These data are coded to the SIC categories. For each Census Metropolitan Area (CMA) we know how many people work in which kinds of activities is known. Unfortunately people do not always work in the same municipality where they live. If the municipality is isolated from other places (e.g., Timmins) the assumption can be made that the residents work in the same municipality that they reside; if it is embedded within a larger economic region (e.g., the City of Toronto or the City of Waterloo) further adjustments must be made. One could shift the scale of analysis from the smaller area municipality to the region as a whole (e.g., the Greater Toronto Area, the Region of Waterloo) or one could turn to other sources of data

on employment. The Ministry of Transportation has compiled journey-to-work data for the major urban regions in Ontario that indicates how many people work in one community (e.g., the City of Cambridge) and live in another (e.g., the City of Waterloo), but these data are not broken down by SIC. Or there may be regional employment surveys that indicate how many jobs of various kinds are found in each component municipality--although they do not always use the same breakdown of commercial activities as Statistics Canada's SIC. The problem, then, is complex; and may require local expertise.

In the present study in the Region of Waterloo, the starting point was the <u>Census</u> of <u>Canada</u> material, augmented by the Region of Waterloo employment survey to provide more spatial data, and Statistics Canada's <u>Labour Force</u> survey, to provide a temporal update. The amount of spatial or temporal detail required will depend on the application of the information.

While there was no alternative to the use of employment data to link the waste generation sample to the projections for the municipalities, the relationship between employment and the volume of commercial activity is very strong (ref. 8). Sales, floor area, and employment are consistently linked together very closely. In the present work, employment is simply the total number of workers, both part-time and full-time--as defined by Statistics Canada. The ratio of part-time to full-time employees is consistent across each SIC sector, and the number of each type of employees should vary through time with the level of sales. Both employment and sales vary slightly from season to season (depending on the type of commercial activity). Early summer data (as used herein) provide a reasonable proxy for the annual levels as indicated by indices of seasonality computed by Statistics Canada (see ref. 16). These indices allow us to calibrate the seasonal effects at other times of the year.

#### 2.2.3 Statistics Canada Employment Data

The <u>Census of Canada, 1986</u> gathers information about occupation, type of firm and place of work from a twenty percent sample of households. A special tabulation of these data provided information about the number of employees in 36 different commercial sectors for each CMA in Ontario. The basic tabulation is by place of residence, which is not a problem for a regional municipality as a whole, but other "journey-to-work" tabulations indicate how this employment is allocated by municipality within the Region. These data can be updated by reference to the monthly survey of "The Labour Force" which estimates employment for each CMA, including Kitchener-Waterloo.

#### 2.2.4 Regional Municipality of Waterloo Planning Information

The Regional Municipality of Waterloo, encompassing the cities of Kitchener, Waterloo and Cambridge, and four smaller Townships of Woolwich, Wilmot, Wellesley and North Dumphries, is located about 110 kilometres west of Toronto and about 60 kilometres northwest of Hamilton. The population of the Region (1988 Municipal Directory information) was 342,030. Information from an employment survey conducted by the Region's Planning Department provided additional information about the number of firms and employment in commercial activity in each of the local municipalities within the Region in 1989. The sectoral categories differ slightly from those used by Statistics Canada so the data could not be used directly in the estimate of waste generation. Instead, the information was used to estimate the share of Regional waste that is generated by each municipality.

### 2.3 Field Work: Methods

#### 2.3.1 Personnel

The field crew consisted of three people; two were university graduates in environmental science and one was a college student in mechanical engineering technology. A basic background in science or engineering was deemed desirable because of the quantitative aspect of the work. The commercial portion of the Ontario Waste Composition Study was an exercise in quantitative analysis of commercial wastes conducted under field conditions, using skills learned in technical courses that are part of science and engineering education.

The crew received instruction on recognizing the categories of plastic and paper from R. Buggeln (Superintendent of Industrial/Commercial Waste Reduction), Region of Waterloo. Because the focus of the waste composition study was on method development, the crew was instructed to be critical of their procedures. The crew was encouraged to set aside all materials that were difficult to categorize, describe them in writing and include them in a 'miscellaneous' category (see Section 2.3.7 below).

### 2.3.2 Contacting Businesses

The field crew had considerable familiarity with a variety of businesses in the Region of Waterloo and they were able to recommend many companies to contact for the study; the Yellow Pages in the phone directory were also consulted for the names of firms. The decision on how best to approach businesses was left up to the field crew, after considering two alternatives: (a) contact by telephone and (b) direct company visits.

The field crew quickly realized that the most practical and efficient method of obtaining permission from local businesses to participate in the study was from a personal visit from the crew members themselves. The approach of contacting the

firms by telephone was very time consuming and was inherently very unsuccessful. In the direct approach, store owners or managers could see first hand, who they would be dealing with. The waste study could be discussed in detail and questions could be answered and the logistical problems at each location could be assessed. A business card from the Region's Recycling Office legitimized the crew's intentions and a rapport between the field crew team and the business could be established. In fact, more than 90% of the businesses directly approached agreed to participate in the study.

### 2.3.3 Scheduling Waste Collection

One objective of the study was to obtain a "snap shot" of the composition of waste generated in a week by commercial businesses. Therefore, waste collections for the study were tailored to the waste collection for each business. In the simplest case (i.e., once a week collection), the crew visited the company 12 to 18 hours before the bulk-lift refuse bin was scheduled for dumping and removed the accumulated waste. Whenever Monday was the collection day, the crew had to make their collection on Sunday.

Many businesses had to be visited 3 or more times in order to obtain a week's worth of waste. In some cases, businesses stored their waste, especially if the putrescible content was low, in order to save the crew repeated trips.

### 2.3.4 Special Documentation

A letter from the Ministry of the Environment authorized the collection of the waste from commercial businesses for purposes of the composition study. The private waste hauler participating in the study requested and received a letter from the Region confirming the confidentiality of the waste information obtained in the study.

The procedure to obtain Ministry approval for solid waste sample collection by municipalities undertaking waste composition studies is as follows:

A letter requesting Ministry approval for temporary collection of solid waste samples shall be mailed by the interested municipality to:

Mr. Dave Crump Operations Coordinator Operations Division Ministry of the Environment 14th Floor, 135 St. Clair Ave., West Toronto, Ontario M4V 1P5

The letter shall include, but not be limited to the following type of information:

- · Background and reasons for undertaking the study.
- Study objectives.
- Study approach.
- Contractor's name.
- Collection area.
- · Approximative number of samples to be collected.
- · Approximative weight of each sample.
- · Estimated duration of the project.

# 2.3.5 Equipment Used in the Waste Study

The following list of equipment includes a rented vehicle and purchased equipment:

- one 4.3 m. (14 ft.) cube van (for collection of bagged refuse);
- one electronic platform scale (150 kg capacity, Accu Weigh Model PAK-150 (electronic, battery operated scale with digital read-out), Exact Weight Scale Inc., Toronto, Ontario);

one -electronic bench scale (500 g capacity, Accurat, model 3670)

- one chicken wire "crib": 1.2 m. (4 ft.) x 1.2 m. (4 ft.) x 1.3 cm. (1/2 in.) plywood base; 0.6 m. (2 ft.) high chicken wire and 2.5 cm. (1 in.) x 5.1 cm.(2 in.) furring sides. Nailed to the underside of the crib floor was a square frame which permitted the crib to be centred on the bed of the platform scale; the crib was used for weighing the refuse as it was being collected from the firms;
- 40 30 litre polyethylene garbage cans; these were used as containers into which sorted refuse was placed;
- one broad-mouth aluminum shovel; used for cleaning up spills;
- one broom; used for cleaning up spills and sweeping out the vehicle;
- one staple gun and 0.95 cm. (3'8 in.) staples for construction and repair of chicken wire dividers and crib;
- one claw hammer; 5.1 cm. (2 in.) common nails: used in the construction of the crib.

Personal Safety Equipment:

- a) Certified steel toe safety boots
- b) Coveralls
- c) Orange safety vests
- d) Hard hats (at the landfill)
- f) Rubber safety gloves
- g) Particle filter masks (dust in garbage bins)
- h) Complete first aid kit (in truck)
- i) Tetanus/polio vaccination (optional: diphtheria, Hepatitis A and B).

### 2.3.6 Waste Collection Methods

In the Regional Municipality of Waterloo, private waste haulers are usually contracted to remove the waste from commercial businesses, except in the downtown core of Kitchener and Waterloo where waste collection was three times per week or daily, respectively. The commercial haulers provided bulk-lift refuse containers of various sizes (2 to 8 cubic yards) in which a firm's waste was accumulated and picked up as required. In most cases, wastes were placed, loose, into the bulk bins; several businesses used compactor type bulk refuse containers.

Waste sampling procedures varied depending on whether the waste was loose or compacted. In the former case, the entire contents of the container were unloaded, weighed in a chicken wire wood "crib" mounted on a scale (see Figures 2 and 3) and placed in 4' x 4' x 4' heavy duty corrugated containers ("gaylords") in the back of a cube van and taken to the Waterloo landfill site (parking lot of the Recycling Office) for sorting (see Figure 4).

Unloading waste from a compacted entanglement of loose and bagged refuse in a 6 or 8 cubic yard bin was very difficult. It was decided that only half of the contents of the bin could be conveniently and efficiently unloaded and weighed, given the arduous task and the time requirement. The weight of the entire bin was estimated on a volume basis from the weight of the sample that was removed, i.e., usually several hundred kilograms. All loose waste was set aside for sorting; bags of refuse were randomly placed into two piles, with an equal number of bags in each pile. One pile was randomly selected for sorting, the other pile was returned to the bin. (See Section 2.3.4)

### 2.3.7 Sample Sorting and Data Management

The commercial waste composition data sheets (Table 4) were used for logging the weights of the various waste materials encountered in the samples. After sorting the waste into categories, each category was weighed and its relative contribution to the total sample weight was determined, i.e., percent of the waste composition. Waste materials that could not be easily categorized, were separately identified (described and weighed) on a "miscellaneous" table, accompanying the main waste composition table for each sample. The total weight of materials in the "main" and "miscellaneous" lists equalled 100% of the sample weight.

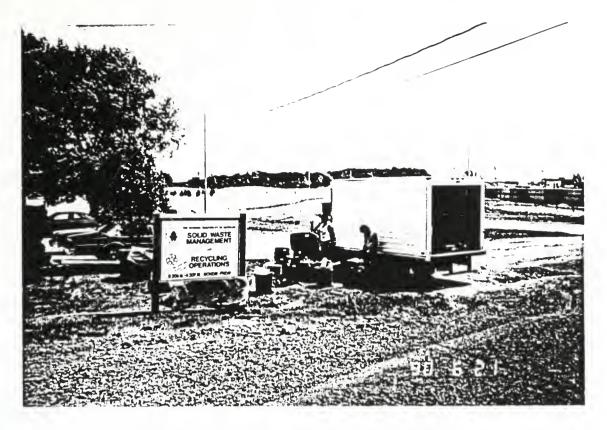

FIGURE 4: SORTING A WASTE SAMPLE AT THE LANDFILL SITE

SECTION 3 RESULTS

### 3.0 <u>RESULTS</u>

### 3.1 Waste Composition of Commercial Groups

A brief summary of the principal components in the waste streams from each of the two-digit SIC commercial groups is presented in the following sections. Each SIC group is listed separately. A complete waste composition for each of the samples is included in Appendix B. Table 7 summarizes the waste compositions of the 16 SIC groups.

The principal components of the waste streams sampled are in the following sections. Where more than one sample was taken, the mean percentage is shown ("n" indicates the number of samples sorted).

# 3.1.1 SIC 17--Leather and Allied Products Industries

SIC 1712--footwear manufacturer (n = 1)

The principal components, by weight, of the waste sampled from footwear manufacturing firms were:

| textiles/leather/rubber |  |
|-------------------------|--|
| wood                    |  |
| OCC                     |  |

### 2.3.8 Data Obtained for Per Employee Waste Generation Rates

Two sampling methods were used to determine the quantity of waste generated at each firm. In the first method, the field crew weighed the waste in the refuse containers before putting the waste in the cube van for removal to the Waterloo landfill site for sorting. As noted above, the frequency of waste collection at each firm was obtained from the owner or manager. The field crew obtained the employment figure for each business at the time of the interview or by telephone.

When it was not possible to obtain the number of full- and part-time personnel from each firm, we used the figures for total employment were used in the regressions of employment versus waste quantity. This is compatible with the data gathered by Statistics Canada.

The first method enabled us to get waste quantity information from small and medium size businesses. The method was very labour intensive and time consuming but worked well for small loads of loose waste. The method was not satisfactory for refuse compacted in 6 to 8 cubic yards containers. The latter containers were frequently encountered at some of the larger locations.

The second procedure was applicable to all bulk containers irrespective of bin size or degree of waste compaction. A scale initially developed to weigh loads of sand and gravel carried in the scoop of a front end loader has been adapted for use on overhead (front-end) loading garbage trucks. The scale works off of the hydraulic lift system that raises and lowers the arms of the bin hoist. A Wray-Tech Model WT4000/6000 (obtained from Woolsey Equipment Sales Ltd., Ottawa) was installed on an overhead packer truck and calibrated with the assistance of the Toledo Scale Company, Hamilton, Ontario.

The bulk waste weighing procedure was a two-step process. First, the bin and waste contents were weighed. Then the contents of the bin were dumped into the truck and the empty bin was weighed. The weight of the bin contents was

determined by subtracting the weight of the empty bin from the weight of the bin plus contents. Again, employment data were obtained for these firms, either by telephone or directly visiting these firms after the waste had been collected.

As noted above, participants in the study were assured of confidentiality of the waste generation and composition information. (NOTE: no locations will be identified by name in this report).

Bin collection frequency was determined from the hauler's records and a daily generation rate (kg/day) of waste was determined for each firm. At the conclusion of the field work, the employment and waste generation data were plotted on separate graphs for each of the commercial groupings. The length of the "work week" was different for different SIC groupings. Some businesses are open 7 days a week (restaurants, hotels, etc.) and some for 6 days (supermarkets, banks, automobile dealerships, etc.). Some printing shops were the only commercial businesses included in our study that operated on a 5-day work week.

#### 2.4 Estimates of Average Per Employee Waste Generation Rates

Each sample observation provided information on the number of employees and the total weekly waste generation for the establishment. This permits two different kinds of statistical generalization. First, it is possible simply to divide the total waste by the number of employees to obtain an estimate of waste generation per employee. Several of these estimates can then be used to determine average values and standard deviations.

Second, more information can be extracted by plotting total waste against employment for each observation. This provides: (1) a visual pattern of the overall variability in the results, an evaluation of the relation between waste generation per employee and size of store (e.g., are big stores more or less efficient with respect to waste generation?); (2) a measure of the waste reduction efficiency of individual

2-13

stores relative to the group; and (3) an evaluation of the effectiveness of the sample selection in relation to store size.

By fitting a regression line to the graph we obtain another measure of the regularity of waste generation, i.e., the regression coefficient  $r^2$ . Another estimate of the relation between waste generation and number of employees is the slope of the regression line (b).

In the next step in the analysis, estimates of waste generation per employee are used to estimate total waste generation within the study area. Either the mean value of waste per employee or the regression slope (b) could be selected. The regression slope was used as long as it was adjudged reliable; otherwise the mean value was used. The reliability depends on both the regression coefficient (over 0.5) and the scatter of observations on the graph. A sample with a wide variety of different stores sizes was deemed acceptable. Those where the observations were clustered together around the same size store were rejected. In the ideal case, where there is perfect correlation between waste generation and employment, the intercept (a) is expected to be zero and the mean value should equal the regression slope (b). For further discussion of regression analysis the reader should consult Modern Elementary Statistics (ref. 6).

### 2.4.1 Estimates From Average Waste Weight Per Employee Data

For each SIC group of commercial business, the daily waste weight generated at each firm was divided by the number of employees to obtain the weight of waste per employee per day. An <u>average</u> estimated waste generation rate ( $\pm$  1 Standard Error) was calculated for the SIC sector from the sample data.

#### 2.5 <u>Estimation of Waste Generation by Commercial Sector in the Regional</u> <u>Municipality of Waterloo</u>

The estimation of commercial waste generation for the Regional Municipality of Waterloo combines two kinds of information. First, various employment data are used to estimate total commercial employment and employment for various types of commercial activity in municipalities within the Region. Second, the field work provides estimates of the amount of waste generated per employee by type of commercial activity. By combining these two kinds of information the final estimate of commercial waste generation is obtained for the Region and its area municipalities.

Consider the breakdown of employment by municipality (Table 5). Note first, the great size range among spatial units. Kitchener is approximately ten times the size of Woolwich and almost 100 times larger than Wellesley. It is much more important to make accurate estimates for the larger places than for the smaller ones. Second, the share of employment in commercial jobs ranges from 30.2 percent in industrial Cambridge to 41.7 percent in Kitchener with its downtown concentration.

(Note: Familiarity with the local economic structure is required to make minor adjustments to Statistic Canada employment information where needed).

For the Region as a whole, the share of commercial jobs was 32.8 percent in the 1986 <u>Census</u> and 38.7 percent in 1989 according to the Region's Planning Department--a difference that reflects variations in definitions in the two data sets. Despite these differences, the regional employment survey permits us to estimate the share of regional commercial employment to be allocated to each municipality (see the fourth column titled % Jobs in Table 5). This should assist in estimating the share of commercial waste generation.

### 2.6 Sources of Potential Error in Employee Waste Generation Estimates

Table 6 lists the kinds of errors that will affect the accuracy of the employee waste generation estimates presented herein. An estimate of the magnitude and "direction" of the error is also given.

TABLE 6 ACCURACY IN WASTE ESTIMATION - SOURCES OF POTENTIAL ERROR

\*Raw data in Appendix B

#### 3.1.2 SIC 28-Printing, Publishing and Allied Industries

SIC 2819--printing (n = 3)

The principal component, by weight, of the waste sampled from printing, publishing and allied industries was:

#### 3.1.3 SIC 48--Communications Industry

SIC 4813--combined radio/television firm (n = 1)

The principal components, by weight, of the waste sampled from communication firms were:

| fine paper   | 35.1% |
|--------------|-------|
| coated paper | 16.4% |
| food waste   | 14.4% |

The firm had cooking facilities for employees; staff worked in shifts and were on the premises throughout any 24 hour period.

3.1.4 SIC 60--Food, Beverage and Drug Industries (Retail)

- a) SIC 6011--large supermarket (n = 1)
- b) SIC 6012--mid-size grocer (n = 3)
- c) SIC 6019--specialty food (n = 1)

3-2

The overall waste composition for the three kinds of food stores was consistent, but there were large variations in the relative proportions of the components.

The principal components, by weight, of the waste sampled from the three types of food stores were:

| a) lar | ge supermarket: |      |
|--------|-----------------|------|
| food   | waste5          | 3.0% |
| 000    |                 | 6.3% |

| b) mid-size grocers: |       |
|----------------------|-------|
| newsprint            | 27.1% |
| boxboard             | 14.6% |
| OCC                  | 10.2% |
| food                 | .8.2% |

c) specialty food store: OCC ......75.0%

3.1.5 SIC 61--Shoe, Apparel, Fabric and Yarn Industries (Retail)

a) SIC 6111--shoe (n = 2);
b) SIC 6149--mens/womens clothing (n = 4);
c) SIC 6151--fabric/yarn (n = 2)

The major components, by weight, of the waste sampled for SIC 61 group were:

| OCC      | <br>28.7% |
|----------|-----------|
| boxboard | <br>15.3% |

In addition, the following observations were made regarding the principal waste components, from specific types of retail establishments:

| a) shoe stores: |  |
|-----------------|--|
| newsprint       |  |
| boxboard        |  |
| OCC             |  |

| b) | mens/womens | clothing | industries | (retail): |
|----|-------------|----------|------------|-----------|
| ne | wsprint     |          |            | . 19.7%   |
| 00 | C           |          |            | 22.3%     |

| c) fabric/yarn industries (retail): |
|-------------------------------------|
| boxboard 15.5%                      |
| OCC                                 |
| tissues 15.3%                       |

#### 3.1.6 SIC 62--Household Furniture/Appliance and Furnishings Industries (Retail)

- a) SIC 6211--household furniture appliances/furnishings (n = 1)
- b) SIC 6212--household furniture, no appli. furnishings (n = 1)
- c) SIC 6223--appliance, television, stereo repair shop (n = 1)
- d) SIC 6231--floor covering store (n = 1)
- e) SIC 6239--other furnishings, e.g., linen, glassware (n = 1)

On average, the major components, by weight, of the waste steams sampled in this SIC group were:

| OCC                    | •••• | <br>48.9% |
|------------------------|------|-----------|
| textile/leather/rubber |      | <br>11.7% |

- 3.1.7 SIC 63-Automotive Vehicles, Parts and Accessories Industries (Sales and Service)
  - a) SIC 6311--dealerships (n=6)
  - b) SIC 6331--service stations/gas bars (n=3)
  - c) SIC 634--parts/accessories (n = 1)
  - d) SIC 635--vehicle repair (n=3)

The waste streams for SIC group 63 contained an assortment of vehicle accessories and parts, e.g., gaskets, cables, air filters, mixed automotive plastics, spark plugs, lubricants, and paint spray cans (aerosol). A number of waste materials were not included in the survey because they were not recovered from the general refuse disposal bins. Nevertheless, they are part of the solid waste stream generated by this SIC sector. These wastes appeared to be stock piled for separate disposal, e.g., tires, oil solvents in drums, scrap metal, and lead acid batteries. These items were not quantified in the present study and could be included in subsequent work.

The principal components, by weight, of the waste streams for the SIC 63 group of industries sampled were:

| a) dealerships: |       |
|-----------------|-------|
| ferrous         | 25.8% |
| OCC             | 14.8% |

| b) service station: |        |
|---------------------|--------|
| polyolefins         | 25%    |
| OCC                 | .14.3% |
| newsprint           | 12.8%  |

#### 3.1.8 SIC 65--Other Retail Industries

- a) SIC 6521--florists (n = 3)
- b) SIC 6542--bicycle shop (n = 1)
- c) SIC 6562--watch, jewelry repair (n = 1)
- d) SIC 6591--second hand store (n = 1)

OCC and food plant wastes were the dominant components of this SIC group. The following outlines specific SIC groups which were sampled and their respective principal components, by weight:

| a) florists:     |        |
|------------------|--------|
| organic material | 50.25% |
| OCC 1            | 18.51% |

| b) bicycle shop:       |         |
|------------------------|---------|
| OCC                    | . 53.6% |
| textile/leather/rubber | 23.6%   |

| c) watch/jewelry repair: |       |
|--------------------------|-------|
| OCC                      | 35.1% |
| newsprint                | 24.2% |
| fine paper               | 12.1% |

d) second-hand store:

| Fine paper  | 17.0% |
|-------------|-------|
| box board   | 13.3% |
| polyolefins | 13.3% |
| food wastes | 13.3% |

3.1.9 SIC 70-Finance and Insurance Industries

a) SIC 7021--chartered banks (n = 3)b) SIC 7031--trust company (n = 1)

c) SIC 7051--credit union (n = 1)

The principal component, by weight, of the waste sampled from finance and insurance industries was:

It is significant to note that the trust company sampled produced no fine paper; in fact, this firm produced little waste. The total sample weight was 4.45 kg of which 52.1% was food waste. This may be the result of confidential documents being shredded and removed from the building. Future studies may consider addressing this diversion method of waste paper.

3.1.10 SIC 91-Accommodation Service Industries

a) SIC 9111--hotel/motor hotel (n = 4)

b) SIC 9112--motel (n = 2)

The presence or absence of restaurants partially determined the relative proportion of food wastes generated in this group; some establishments had efficiency units so food would also be processed/cooked at those locations. The average principal components, by weight, of the waste streams of the hotels and motels sampled were:

| food waste |       |          |     |    |      |
|------------|-------|----------|-----|----|------|
| OCC        | 10.3% | (ranged: | 1%0 | to | 35%) |
| newsprint  | 14.4% |          |     |    |      |

3.1.11 SIC 92--Food and Beverage Service Industries

a) SIC 9211-licensed restaurants (n = 3)

- b) SIC 9213--take-out restaurants (n = 3)
- c) SIC--hamburger take-out/sit-down restaurants (n = 3)

The principal components, by weight, of the waste sampled from food and beverage establishments were:

| a) licensed restaurants: |         |
|--------------------------|---------|
| food waste               | . 54.8% |
| glass                    | 21.5%   |
| OCC                      | .8.8%   |

| b) take-out restaurants: |         |
|--------------------------|---------|
| food waste               | . 57.6% |
| OCC                      | .9.4%   |
| newsprint                | 6.6%    |

| C)  | "hamburger" | take-out/sit                            | down                  | restaurants: |
|-----|-------------|-----------------------------------------|-----------------------|--------------|
| foc | d waste     | ••••••••••••••••••••••••                |                       | 28.3%        |
| 00  | C           | ••••••••••••••••••••••••••••••••••••••• |                       | 28.0%        |
| coa | ated paper  |                                         | • • • • • • • • • • • | 7.3%         |

#### 3.1.12 SIC 96--Amusement and Recreational Service Industries

- a) SIC 9621--movie theatre (n = 1)
- b) SIC 9691--bowling alley (n = 1)
- c) SIC 9692--amusement park (n = 1)
- d) SIC 9699--horseback riding (n = 1)

The four kinds of amusement activities are very different from each other and the composition of the waste streams have little in common. However, paper, food waste and plastics were predominant. Over the sector, the food waste component accounted for an average 17.7% of the refuse weight. The theatre generated a high percentage of coated paper (15.8%); wood waste, in the form of wood shavings (animal bedding) from the riding establishment was 45.6%.

#### 3.2 Per Employee Waste Generation Rates

#### 3.2.1 Overview Data Handling

For each company participating in the study, a daily, per employee waste generation rate was determined (kg per employee per day). The weight of waste generated by a company during one "work week" was divided by the number of days in their "work week", either 5, 6 or 7. The weight per day was divided by the total number of employees in the firm. An estimate of the employee waste generation rate per day for each SIC group, or sub-grouping, was obtained by averaging the information for all companies in the same SIC group or sub-grouping.

$$\frac{(kg/wk)}{6}$$
 = weight per day

weight per day = employee generation rate per day total no. of employees

#### <u>sum: employee generation rates</u> = average employee generation n (no. of employees) = rate per day

For each two-digit SIC group or sub-grouping, the daily waste generation rate for each firm was also plotted against the number of employees. Linear regressions were calculated for the data and the resulting coefficients representing the employee waste generation rate (the coefficient b in the regression equation: y = a + bx) were compared with the estimates of daily waste generation for the SIC sector, determined by the averaging method.

In the following Sections (3.2.2 to 3.4), the per employee waste generation data are briefly evaluated with respect to the parameters of sample size, data scatter on the graph, regression coefficient and other anecdotal information which affected the decision to use either (1) the regression coefficient, b, or (2) the calculated average, for the SIC sector estimate of the rate of waste generation by employees in that sector.

Table 8 summarizes the estimation of waste generation presented in Sections 3.2.2 to 3.4 and should be referred to for the numerical calculations of the per employee waste generation rates. Figures 5 to 20, showing the distribution of the sample data for each SIC sector, are indicated in each sub-section heading. Numbered data points on these figures indicate sample numbers.

3.2.2 SIC Group 28--Printing, Publishing and Allied Industries (Table 11 & Figure 5)

Printing is considered a "light industry". Although the regression coefficient was 0.61, many data points were clustered at the low employment end of the scale. An average of all the data should be used as the waste generation estimate for the group, i.e., 4.9 kg/employee/day.

#### 3.2.3 SIC Sector 56 - Metals, Hardware, Plumbing, Heating and Building Materials Industries (Wholesale) (Table 12 & Figure 6)

Although this SIC group is considered as wholesale by the classification system, retail hardware and building supply stores have general retail activities as part of their business. Because the regression coefficient, r = 0.97, was strong, the regression estimate for the waste generation rate was used: 5.7 kg employee day.

#### 3.2.4 SIC Group 60 Food, Beverage and Drug Industries, Retail (Tables 13 & 14, Figures 7 & 8)

Per employee waste generation rates for small/mid-size markets and variety stores is lower than that generated by larger "chain-store" supermarkets. For smaller/mid-size stores (Figure 7), the estimated rate was 7.7 kg/employee/day; for larger markets (Figure 8), the average rate was 12.2 kg/employee/day. The regression coefficient for the small store was 0.869 and 0.49 for the large markets. Regression analysis did not give a reasonable estimate for supermarket waste generation because of the scattered distribution of the data.

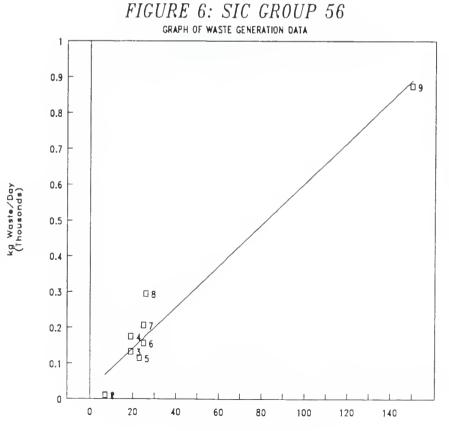

We have attributed 2/3 of the employment in this group to small and mid-size stores; 1/3 to the larger supermarkets. The waste generation estimate for the group is:  $2/3 \times 7.7 \text{ kg/employee/day} + 1/3 \times 12.2 \text{ kg/employee/day} = 9.2 \text{ kg/employee/day}$ .

#### 3.2.5 SIC Group 61 - Shoe, Apparel, Fabric and Yarn Industries, Retail (Table 15 & Figure 9)

The regression coefficient of .0587 was judged to be marginally acceptable, giving an estimate of the waste generation rate of 0.6 kg/employee/day.

#### 3.2.6 SIC Group 62 - Household Furniture, Appliances, and Furnishings Industries, Retail (Table 16 & Figure 10)

A single datum for a large company biased the regression analysis so the average of all the data are used to estimate the waste generation rate which was 1.49 kg/employee day.

### 3.2.7 SIC Group 63 - Automotive Vehicles, Parts and Accessories Industries, Sales and Service

#### 3.2.7.1 SIC Group 631 - Automobile Dealers (Table 17 & Figure 11)

The study sample was relatively large (n = 14) and included firms with a large number of employees. The regression coefficient, r = 0.86, showed a strong correlation between waste generation and employment. Based on the regression, the waste generation is estimated to be 0.87 kg employee day.

Why use the regression value of 0.87 kg/employee/day and not the sample mean (1.4 kg/employee/day), when all but two of the sample data are greater than 0.87 kg/employee/day? In practical terms, these two estimates do not differ significantly from each other; the data plotted in Figure 11 suggest a strong relationship between employment and waste generation (regression coefficient, r = 0.74). Additional sampling would strengthen this relationship further.

#### 3.2.7.2 Group 633 - Gasoline Service Stations (Table 18 & Figure 12)

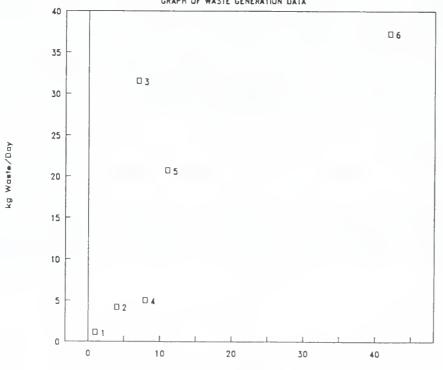

The sample size was too small (n=3) to use the regression estimate. Therefore, the sample average (0.36 kg/employee/day) was used as the waste generation estimate.

|          |            | +/- SE       | 0.063        |

Number of Employees

#### 3.2.7.3 Group 635 - Motor Vehicle Repair Shops (Table 19 & Figure 13)

The wide range of weights over a very small employment range can be accounted for by the waste management practices of many firms. Although scrap metal bins were usually on the company's premises, metal items were routinely discarded in the general garbage bin.

Regression analysis was not applicable to the cluster of data. Therefore, the waste generation estimate of 4.6 kg/employee/day was obtained from averaging the data.

### 3.2.8 SIC Group 65 - Other (Miscellaneous) Retail Store Industries (Table 20 & Figure 14)

The regression coefficient, r = 0.365, was indicative of the wide scatter in the data. Therefore, the average of the sample data (4.94 kg/employee/day) was used.

## 3.2.9 SIC Group 70 - Deposit Accepting Intermediary Industries (Table 21 & Figure 15)

The regression of the data gave an acceptable regression coefficient of 0.825 and thus a regression estimate of 0.16 kg employee day.

#### 3.2.10 SIC Group 91 - Accommodation Service Industries, Accommodation Without Restaurants but with many Efficiency Units (Table 22 & Figure 16)

The regression coefficient was too low to accept the regression estimate. The average of the sample data gave a waste generation estimate of 6.2 kg/employee/day. Although there was no restaurant associated with the facilities, the high waste generation rate is attributed to the efficiency units where long term residents were living and cooking meals. This type of accommodation becomes a residential dwelling and must be treated as a special waste stream.

3-13

#### 3.2.11 SIC Group 91 - Accommodation Service Industries, Accommodation with Restaurants (Table 23 & Figure 17)

The regression coefficient was too low to accept the regression estimate. The average of the sample data gave a waste generation estimate of 1.7 kg employee day. The larger number of employees at these facilities led to a lower per employee wastes generation rate than for premises with efficiency units.

For SIC Group 91 as a whole, we assumed that hotels with restaurants might account for two thirds of the employment for this group.

### 3.2.12 SIC Group 92 - Food and Beverage Service Industries Licensed (Table 24 & Figure 18) and Unlicensed (Table 25 & Figure 19) for Alcoholic Beverages

The regression analyses for the licensed and unlicensed restaurants were similar (regression coefficient, r = 0.77), so the data were combined and analyzed together giving a regression coefficient, r = 0.77. The regression estimate for waste generation for the combined data was 3.0 kg employee day.

## 3.2.13 SIC Group 96-Amusement and Recreational Service Industries (Table 26 & Figure 20)

The data were clustered at the employment end of the scale, so use of the regression value was not appropriate. The sample average of 2.1 kg/employee day was used as the waste generation estimate.

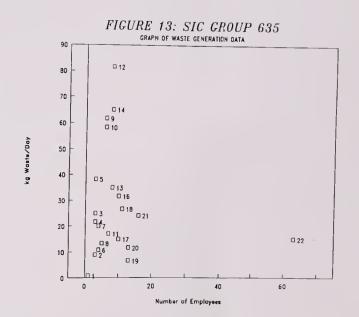

#### 3.3 <u>Wastes Generation Estimates for Other SIC Groups</u>

SIC Group 64 (General Retail Merchandising Industries) includes department stores. A waste generation estimate for these firms was the average of the estimates for similar retail SIC Groups 61 and 62; i.e., 1.14 kg/employee/day. TABLE 19SIC GROUP 635, W(KG/EMPLOYEE/D/<br/>REPAIR SHOPS

Number of Employees

kg Waste/Day

For SIC Groups 71 to 77 (Finance, Insurance and Business Service Industries) wastes generation data were obtained from a study that was conducted for the Ontario Ministry of Government Services (personal communication: Ms. Marook Sidhwa, Regional Coordinator - Toronto East, Waste Management Program, November, 1990). The average wastes generation rate was reported as 1.34 lb/employee/day or 0.61 kg/employee/day.

Because of the similarities in activity, the waste generation estimates for SIC Groups 97 to 99 (Personal and Household Service, Membership Organizations and Other Service Industries) were estimated to be the same as that for banks (SIC Group 70).

As earlier discussed, Table 8 provides a summary of the estimation of waste generation by commercial sectors as discussed above.

### 3.4 Sources of Potential Error in Employee Waste Generation Estimates

Error in the estimates of waste generation for a municipality can occur in two ways. First, the labelled Waste Survey in Table 6 is derived from the evaluation of ratios of waste generation per employee (Section 3.2.1). The error occurs in the sampling procedure, due to store-to-store differences in the ratios; this error can be reduced by increasing the sample size. The results presented in Table 8 suggest that the standard deviation ranges from 10 to 30%.

Difficulty in identifying and clarifying the correct type of business SIC can also contribute to that error, and is more difficult to evaluate. The error depends on the significance of identifiable differences in subtypes of commercial activities, perhaps segmented by location or brand names or product mix. A store incorrectly identified could lead to a sizeable error in a small sample. In this study, local business directories provided the SIC for the businesses. Measurement errors, e.g., weight of waste, should be relatively minor.

The second form of error (possibly embodied in the remainder of Table 6) is related to the estimation of total commercial activity in various sectors, based on various data sources. Each data source has its own problems. Unlike the waste study data, these errors cannot be reduced by increasing the sample size. Census data are comprehensive, but begin with the undercounting bias that averages this percent across the population as a whole. There may be other systematic errors in reporting the SIC; such as, whether the person is actually working, or the location error in the Labour Force survey is derived Most of the of the work place. directly from the sample size, since there is not detailed information on location or SIC. The regional employment survey provides greater spatial detail but carries a high level of error due to non-response and errors in SIC or number of employees. Local governments are not professional data gathering agencies and employers are not required to respond.

The present study is thus an exploratory one, and the sampling errors in the waste survey predominate. As more information is integrated from additional work, and samples become larger and more precisely targeted, these waste survey errors can be reduced and made small, relative to the problems of employment estimations and projections.

### 3.5 <u>Estimation of Commercial Waste Generation in the Regional Municipality of</u> <u>Waterloo</u>

Table 9 disaggregates the various SIC categories from Statistics Canada to conform to the groups used in the present field study. Note that much of the commercial activity can simply be grouped together as office employment. The field study has focused on the variance in waste generation among retail and service activities. The table also contains estimates of total regional employment for each of the commercial sectors. To obtain an estimate of the Region's employment from the CMA data in the <u>Census</u> we simply multiplied by 1.028 to reflect the slight differences in the spatial definition of the study area (i.e., the Region's boundaries are slightly larger than those of Statistic Canada for the Region). To convert the 1986 employment to 1990 employment, we multiplied by the estimated commercial employment growth of 15 percent. The application of growth rates in this manner does not account for fluctuations occurring as a result of economic fluctuations, such as during a periods of recession. The joint effect of these two adjustments is 18.2 percent. These employment estimates are combined with the waste generation per employees to estimate total commercial waste for the SIC group listed.

Finance and service industries have been estimated to produce nearly 40% of the total commercial waste. This may be due to the high number of people employed in these sectors with the Region.

The data in the right hand column of Table 9 are estimates of weekly waste generation rates (kg/employee/week) for 13 commercial SIC Groups. The weekly per employee waste generation estimate for each SIC group was multiplied by the total regional employment for the group to obtain the weekly waste contribution (kg/week) from the SIC group. These calculations are shown in Table 8 (note: the kg/wk are presented in 1,000s, i.e., the actual values are 1,000 times higher than the number entered in the table; e.g., 342 x 1,000 = 342,000.

The total estimated weight generated by the commercial sector is 1,469,400 kg/wk, or approximately 1,469 tonnes/wk (76,388 tonnes year). In 1989, the total waste landfilled in the Region of Waterloo was 439,000 tonnes. Waste from commercial sources is therefore estimated at 76,388/439,000 x 100 or 17.4% of the total tonnage.

Table 5 relates the size of the commercial work force in each area municipality with the proportion of waste generated by the respective municipalities in the Region. Kitchener, Waterloo and Cambridge account for approximately 92% of the commercial waste generated in the Region.

### TABLE 9

### ESTIMATES OF COMMERCIAL WASTE GENERATION

| Activity                                                                                                                                           | Emp1<br>CMA (1986)                                                         | oyment<br>Region <sup>a</sup> (1990)                                        | Waste Generation<br>kg./empl./wk.                                                   | Total Waste<br>kg./wk. x 10 <sup>3</sup>                                                                 |

### 4.0 DISCUSSION

### 4.1 Overview of the Method

#### Waste Composition

Table 7 summarizes the waste streams from the 16, two-digit SIC commercial sectors. Because these are average percentages of the composition of waste samples collected from more than one company, the total will not add up to 100%. It is apparent that paper predominates as the major category of waste. In most cases, OCC is the largest fraction of the paper waste. Food waste from restaurants and markets is a significant portion of the waste streams from these businesses.

The waste composition data are presented as percentages of the total composition and indicate the relative proportion, i.e., the general picture of various waste materials generated by commercial businesses. However, to be useful to waste management personnel in municipalities, the waste composition data must be accompanied by quantitative information on waste generation. For example, if OCC is identified as a significant percentage of the waste from a particular commercial business the following questions must be addressed:

- 1) How many similar businesses are there in the municipality?
- 2) How much OCC is generated by all of those businesses in the municipality?
- 3) What percentage of the waste stream is represented by OCC in the other commercial groups?
- 4) What is the total tonnage of cardboard from all groups?

#### Waste Quantity

DeGeare & Ongerth (ref. 3) reported a relationship between the quantity of waste generated by commercial businesses and business employment. In about 50% of the two-digit SIC groups that we studied, reasonable regression coefficient values (r) for the relationship between waste generation and employment were obtained (Table 8). In the case of the remaining SIC sectors, one or more reasons were proposed to explain the poor regressions; e.g., sample size of businesses was too small; data were clumped; interfering waste management practices; etc. In these cases the average per employee waste generation rates were used in calculations rather than the value for 'b' (slope) in the regression equations.

On the basis of the DeGeare-Ongerth relationship, the waste generation rates for retail commercial activities were estimated on a Region-wide scale, using suitably adjusted Canada Census data for the Regional Municipality of Waterloo (see Section 2.0).

Referring to the OCC example above (i.e., where a relatively high proportion of OCC is identified in the commercial waste streams in a municipality) waste management planners can estimate the quantity of OCC generated by all of the commercial groups in a municipality, once they know the following: (1) per employee waste generation rate for each SIC group; (2) the total employment in the commercial groups within the municipality; and (3) the quantity of OCC in each of the waste streams that were studied as part of this waste composition study, i.e., those commercial activities that are related to residential consumption. (Note: this forms the basis of estimates in data base projections.)

### 4.2 Evaluation of the Methods

### 4.2.1 Waste Composition of Commercial Businesses

#### Timing of the Study

If the waste composition study had been conducted two or three years ago in the Region of Waterloo, we could probably have stated with certainty that the composition of the waste stream had been adequately assessed by our study Presently however, waste reduction and waste diversion are being methods. more frequently practised as company policy or by conscientious employees who take recyclable materials from places of work to recycling locations in municipalities or home to their Blue Boxes. We expect that these activities have reduced the quantities of some materials that otherwise would have been discarded in the bulk refuse containers. The impact of these waste diversion activities would be greater in companies with fewer employees than in those with larger employment. We cautiously regard the composition data as a best estimate under constantly changing circumstances. This study did not attempt to quantify the amount of materials being diverted from a company's waste stream; the waste composition, therefore, does not include those materials which were being diverted (if any) through any outside agencies.

Because of the scope of the work, it was not possible to design a waste sampling program that would permit the collection of a sufficient number of samples so that statistical analyses could be applied to the waste composition data. It must be pointed out that this study was a prerequisite study; the level of variance between the estimated and actual waste composition is not known. More field work must now be done in other municipalities to augment the data contained herein.

#### Waste Composition Variability

Does one expect a large variation in the composition of the waste streams generated by commercial businesses throughout the year? Given the "predictable character" of retail activities carried on within each SIC group, there is no reason to expect a significant variation in the composition in the waste generated by business within a given sector.

It is expected, however, that there may be variations in the quantity of waste, with increases occurring at certain times of the year, e.g., Christmas holidays, year-end inventory, etc. However, as was pointed out earlier (see Section 2.0), retail activity is dependent on consumer habits. Consumer waste generation is reportedly consistent, varying +/-10% of a yearly average over three quarters of the time (cf. Vesilind & Rimer, ref. 17). The implication of this consistency is that seasonal variations in residential refuse generation patterns will be mirrored in many of the commercial retail sectors. Financial institutions may also exhibit predictable fluctuations in waste composition and/or quantity, that may be correlated with cyclic business-related activities.

### 4.2.2 Per Employee Waste Generation

### Waste Collection

Unloading waste from refuse bins by hand was unpleasant, time consuming and very awkward, particularly for compacted refuse. Nevertheless, this method enabled us to obtain the total weight of refuse discarded by 65 of the businesses surveyed in the study with four samples from "light industry". The remainder of the refuse weight data from 80 companies were obtained using a scale mounted on a garbage truck (see Section 2.0) and 10 samples were "dedicated" loads from single businesses, with load weights from landfill scalehouse data. A number of firms were sampled twice during the study. The total number of samples was 212 (Table 8).

The truck collection route varied each day but, in general, the Monday route was the same each week, Tuesday routes were similar, and so forth. Occasionally, additional pick-ups were radioed to the driver, for example, businesses scheduled for "on-call" collections, sporadic customers which require pick-ups once every three to four weeks, etc. The truck-mounted scale greatly enhanced the data collection expectations initially envisaged for the study. It should be noted that the weighing procedure significantly increased the length of time that the driver had to spend at commercial customers on the collection route.

#### Per Employee Waste Generation

The economic slow-down has been correlated with a reduction in the amount of refuse entering the Region of Waterloo landfill sites (personal communications, R. Martiuk, Director of Solid Waste). Notable reductions in construction refuse reflect the low number of new houses being built. In theory, a reduction in commercial sales will be followed by a reduction in the retail work force. The relationship between waste generation and employment will go through a period of adjustment until the SIC sector-specific waste generation versus employment ratio is re-established. At the present level of sophistication of this study, it was not judged important to account for these potential perturbations in the work force.

### 4.3 <u>Graphical Presentation of Waste Generation Versus Employment---</u> Potential Method to Evaluate Company Waste Management Performance?

Graphs of the study data for waste generated by businesses, versus employment (Figures 5 to 20), display the variance of "waste management performance" that has been encountered in the sample of businesses. In theory, the waste generated by businesses should be closely correlated with employment and the data should tend to fall about an imaginary linear projection line. If there are data that are greatly removed from the linear tendency of the majority of the sample points, those businesses may be targeted for investigation with respect to their waste management practices. For example, a business with exceptional

waste minimization efforts will show up as a data point that is well below the general linear grouping of businesses; a business with poor waste management policies will show up as a data point that lies well above the linear grouping of businesses.

Therefore, municipalities are advised to plot the employment-waste generation ratios in order to "get a feel" for practical problems that they can address in specific companies. A simple average of employee waste generation rates would suffice if rates, alone, were important.

While the per employee waste generation rates are simply taken as the values of 'b' (slope) in Table 8, one may legitimately modify these rates, based on the number of employees in a given firm. In other words, one may divide the value for 'a' (kg/day) by the number of employees in a firm and add this quotient (in units of kg/employee/day) to the value of 'b'. As employment increases, the impact of the 'a' (employment) on the value of 'b' will decrease. No company-specific adjustments were made to waste generation estimates because we were interested only in an average estimate, representative of the SIC group as a whole, i.e., the value of 'b' alone.

### 4.4 Usefulness of Landfill Data in Estimating Commercial Refuse Quantity

Generally, there are three systems for the collection of waste from commercial sources and delivery to landfill sites: (1) residential garbage trucks and (2) front end (or over-head) packer trucks and (3) "dedicated loads" from large supermarkets and large malls. Residential garbage trucks frequently make collections from commercial businesses as part of their daily routing through a municipality. The load is weighed at the scalehouse and the weight is normally recorded as "residential". The fraction of the waste collected from commercial businesses cannot be accurately determined under these circumstances.

Haulers using front end packer trucks frequently make between 25 and 50 refuse collections from customers before proceeding to a waste facility. A typical collection route for one of these trucks may include stops at: schools, senior citizen's homes, commercial businesses, industries, hospitals, condominiums, apartment houses, malls, etc. It is apparent that no matter what category is chosen to designate the "source" of the waste, when the load is weighed at a disposal facility, the choice will not reflect the heterogeneity of the waste in the truck. It is normal for these loads to be recorded as either "commercial" or "industrial".

Given the nature of the waste delivery systems from generator to transfer station or landfill site, most of the scalehouse data do not give a reliable picture of commercial and industrial waste generation, and to use that data in estimating waste composition would be misleading. Yet, scalehouse "records" are the basis for the widely held generalization that residential waste is "40%" of the total waste stream and commercial and industrial waste accounts for "60%". There is good reason to doubt the accuracy of this or any other percentages that rely on scalehouse weight data. The method that we have developed in the present study will enable municipalities to make a reasonable estimate of the waste generated by the commercial business sector. The method described in Volume I of the Waste Composition Study can be used to estimate the residential waste stream.

### 4.5 Verification of the Employee Waste Generation Estimates

In the absence of an alternative method to directly estimate the employee waste generation rates, one must defer to a comparison of the data with published literature values. Such a comparison is given in Table 10. With the exception of the generation rates for the financial operations, the results compared favourably with those of Rhyner & Green (ref. 14), especially if one were to estimate limits of  $\pm$ 10 to 30% around both sets of data.

The following verification method is suggested in future studies. Using small "strip malls", estimate the total waste generation rate for each business, using the SIC per employee waste generation rate estimates (from this study) and the employment figure for each business. Compare the estimated sum of waste generated for the entire sample mall with the actual weight of waste produced by the mall.

### 4.6 "Light Industry"

The <u>Standard Industrial Classification</u> system uses the term "industry" throughout (e.g., "Retail Trade Industries"), but no categorical distinction or definition is given to the term "light", with respect to any kind of industry. Commercial businesses are also called industries, so one cannot look to the SIC code to assist in distinguishing "light" industry from "heavy" industry.

Semantic arguments and clear problems of nomenclature aside, an arbitrary decision was made to call the shoe manufacturing industry (SIC 17) and the printing industry (SIC 28) "light industry". No special methods were applied to the data gathering procedures for these businesses and therefore the data are considered tentative. This study describes sampling procedures for commercial activities that closely serve the residential sector. Longer term sampling procedures are needed to assess industrial waste stream characteristics.

### 5.0 CONCLUSIONS & RECOMMENDATIONS

### 5.1 <u>Conclusions</u>

 Waste composition and per employee generation rates have been estimated for the commercial businesses in the Regional Municipality of Waterloo. The methods used in the present study provides direct estimates for 52% of the total employment in commercial business in the Region and indirect estimates for 100%. Thus, estimates of the waste generated by a segment of the commercial sector of the municipality have been made for the first time.

The total annual tonnage received by the two Region of Waterloo landfill sites in 1989 was 439,000 tonnes. Based on the results of the present study, the commercial sector contributed an estimated 76,388 tonnes, or 17.4% of the total weight.

 The most commonly encountered waste material in commercial refuse was corrugated cardboard (OCC) which ranged from a low of 4.0% to a high of 49.0% of the weight of refuse generated by the firms which were sampled.

The wide range in OCC content may be the result of some firms separating used OCC for recycling, possibly in anticipation of the proposed ban on the landfilling of OCC within the Regional Municipality of Waterloo in 1991.

Variations observed in the composition of other waste streams may be due to recycling activities, either under the auspices of company-wide programs or by conscientious employees who took materials to recycling locations in the municipality or home to their own Blue Boxes.

 The statistical reliability of the waste composition data for some of the SIC groups is questionable because of the small number of waste samples that were sorted. Nevertheless, the data indicate the general proportion of materials in the waste streams from the 16, two-digit SIC groups that comprise the commercial business community in the Region. Waste from 65 businesses was sorted.

- 4. The installation of a truck-mounted scale, used to determine the weight of refuse in 2 to 8 cubic yards refuse bins, enabled us to obtain waste quantity data from an additional 80 commercial businesses. For estimating the per employee waste generation rates, this method is more efficient than the labour intensive method, used in the waste composition part of the study, in which the crew unloaded the refuse bins by hand to determine the total weight of the waste in the bin.
- 5. During the course of the study, insights were noted regarding the effectiveness of waste management practices of some firms. For example, for automotive repair businesses, it appears that employee's tend to use the general refuse bin for discarding metal waste materials, despite the fact that a scrap metal bin has been made available.

Such insights, when communicated to the management of the firm provide an immediate opportunity to help that firm improve the efficiency of their recycling efforts.

There is also an indication that differences exist in per employee waste generation rates in small grocery stores and in larger supermarkets.

The demonstrated method for estimating the rate of employee waste generation has the potential to be used as a waste management tool by municipalities. The distribution of the daily waste generation rates versus employment data, exhibited in the graphs for each SIC sector, could enable municipal waste management personnel to prioritize their "remedial" waste reduction efforts by planning to visit those companies whose waste generation rates seem out of line with the general waste-to-employee relationship.

### 5.2 <u>Recommendations</u>

The methods employed in the commercial portion of the Ontario Waste Composition Study have been demonstrated on a selection of commercial businesses in the Regional Municipality of Waterloo. Within the commercial sectors in the Region there is a relatively high awareness of waste diversion options that will reduce waste disposal costs and encourage recycling. Therefore, we cautiously regard the qualitative and quantitative data presented herein as a best estimate under constantly changing circumstances.

This report has developed a procedure for estimating the amount of waste generated by commercial activities within Ontario urban areas and began with the process of integrating the complex data inputs required. What are the next steps?

The study has employed a two-stage estimation process: (1) the development of ratios of waste generation per employee; and (2) the estimation of commercial employment composition for the municipality as a whole. Each step poses different problems. The following recommendations are submitted:

1. The waste generation and composition data base will require many more samples in order to cover the full range of commercial activities. No one study will have the resources to undertake a complete evaluation; the research results must be accumulated over many studies and evaluated over time. Fortunately, there is no inherent reason that a business in any part of the province cannot be used to estimate waste generated elsewhere--unless local waste management policies differ significantly.

This means that each study should use the same SIC identification to code commercial activity and the same methodology for measuring waste output and composition. A central agency (e.g., the Ministry of Environment) may have to take the responsibility for organizing and evaluating the data.

- 2. It will also be necessary to monitor any changes over time in waste generation that may reflect innovations in policy, technology or corporate behaviour. The date of each sample must be retained and/or it may be necessary to identify sample locations that can be restudied over time in order to minimize sampling error.
- 3. To better understand the effect of recycling behaviour on the data gathered, it is recommended that employees/management of participating firms be asked to describe the nature and extent of any source separation recycling activities.
- 4. The immediate priorities for sampling can be identified from the results of this study. Those commercial activities that employ large numbers of people must be further investigated in order to improve sample size and reveal any significant variation within the SIC groups; this includes the diverse set of office and financial activities. Conversely, those activities with a high rate of waste generation per employee, such as food stores and restaurants, must be sampled repeatedly because of their importance to the overall waste generation. Those sectors where the observed sample variance (standard deviation) is high require larger samples to improve overall accuracy, possibly by isolating subgroups within the SIC. Activities that generate policy-relevant waste materials should be given special attention.
- 5. The future development of employment estimates requires two divergent approaches. First, substantial savings may result from a centralized standardized analysis of employment that applies the same set of data, techniques and projections to all urban areas--much as the Ontario Statistical Centre has developed a common set of population forecasts.

At the same time, municipalities have better information about local peculiarities and exceptions to the employment structure. These special cases, e.g., community colleges, tourist attractions, shopping concentrations,

as well as manufacturing activities, may require special attention by a local agency.

## ACKNOWLEDGEMENTS

#### ACKNOWLEDGEMENTS

Gore & Storrie Limited wish to acknowledge the assistance provided by the Regional Municipality of Waterloo for the commercial portion of the Ontario Waste Composition Study. Mr. Dick Buggeln of the Region co-ordinated the field work and wrote significant portions of the text.

The concept for the field study was developed following the advice of Dr. Virginia Maclaren that led to extensive discussions with Dr. Jim Simmons (both faculty members in the Geography Department, University of Toronto). Dr. Simmons worked with the <u>Canada Census</u> employment information and accessed other employment data bases in order to develop a picture of employment in the retail commercial businesses in the Regional Municipality of Waterloo. Dr. Simmons also assisted in the evaluating the field data and writing portions of the text. The project clearly benefitted from Dr. Simmons' many crucial contributions.

The field crew: David Fox (Gore & Storrie Limited), Ritchard Stevenson and Lisa Morgan (both from the Region of Waterloo) were responsible for contacting the companies, organizing an often complicated waste collection schedule and sorting the waste. They were a dedicated crew and their efforts are greatfully acknowledged.

A considerable portion of the field work was conducted with the participation of Big Bear Services, Waterloo, Ontario, and the cooperation of Messers. Bob Knarr, Gary Bell and Bruce Storrer.

Report preparation assistance was provided by David Fox, Brock Harrington, Rob Flindall, Debra Hayes and Chris Taylor of Gore & Storrie Limited, with additional support from Adam Buggeln and Barbara St. Hill. The Project Managers for Gore & Storrie Limited were Les MacMillan and Jeff Flewelling.

We greatfully acknowledge the strong ongoing support and assistance of Messrs. Neal Ahlberg, Brendan Killackey and Dan Ionescu, Waste Management Branch, Ministry of the Environment.

#### DISCLAIMER

This report was prepared for the Ontario Ministry of the Environment as part of a ministry-funded project. The views and ideas expressed in this report are those of the author and do not necessarily reflect the views and policies of the Ministry of the Environment, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

#### INFORMATION FOR THE READER

The results of the Ontario Waste Composition Study appear in three volumes.

Volume I contains the results of the residential portion of the Ontario Waste Composition Study. The emphasis in Volume I is on the development and testing of a method that municipalities can use to estimate per capita generation rates of residential refuse. The field work for Volume I took place in East York, Fergus, and North Bay, Ontario.

Volume II contains the results of the commercial portion of the Ontario Waste Composition Study. Waste generation data for two light industrial businesses are also provided in Volume II. The emphasis in Volume II is on the development and testing of a method that municipalities can use to estimate per employee waste generation rates and, further, to estimate the quantity of waste generated from all commercial sources. The commercial component of the study took place in the Regional Municipality of Waterloo.

Volume III is a "user friendly" manual that outlines the procedures for conducting residential and commercial waste composition studies in municipalities of Ontario. While every effort has been made to present as complete a description of the method as possible there will be instances where the persons conducting a waste study will find it necessary to make adjustments to this method to suit particular circumstances.

Volume III is divided in two parts. Part A provides a description of the methodology used to conduct the Residential Waste Composition Study. Part B describes the methodology used to conduct the Commercial Waste Composition Study.
